尊 axisA. View of receptors, which in turn are involved in the process of metabolism, with particular attention to the role of enzymes. The metabolism of glucose, in particular, is a key process in the regulation of energy and nutrient metabolism in cells. This process involves a series of enzymatic reactions that convert glucose into energy in the form of ATP, which is then used by the cell for various metabolic processes. The regulation of these reactions is crucial for maintaining cellular homeostasis and is achieved through a complex interplay of metabolic intermediates and regulatory proteins.
